The Ship of Theseus Cartel

Neutral founders, neutral successors

Subramanyam Sahoo | Independent researcher

RESEARCH DRAFT - REVIEW BEFORE SUBMISSION

Component block diagnostic. Use the campaign report for the six pooled primary comparisons.

Abstract

Replacing an AI pricing agent may leave the observations that supported its behavior intact. We test whether coordinated high-profit pricing survives replacement of both founding agents, and whether sequential replacement differs from a simultaneous replacement made at the same final turnover time. This neutral study branches identical founder histories into 13 conditions, including inherited-history removal, synchronized resets, competitive counterfactual histories, and a one-round deviation probe. The recorded dataset contains 312 completed post-founder branches. Primary outcomes are normalized profit gains relative to verified Nash and joint-monopoly benchmarks; paired differences are averaged within product contexts before uncertainty estimation. Explicitly instructed positive controls are retained and reported on the test contexts. The design reuses the supplied pricing environment while correcting a missing currency-scale derivative in its equilibrium solver. Retail records supply descriptive contexts and scales, while demand remains a structural assumption. The deviation probe measures response and recovery but does not uniquely identify strategic punishment. The estimates below therefore concern the specified simulator, prompts, checkpoints, and finite horizon, not real-world cartel prevalence or intent. This automatically populated draft requires human review, contextual interpretation, and transfer to the official submission template.

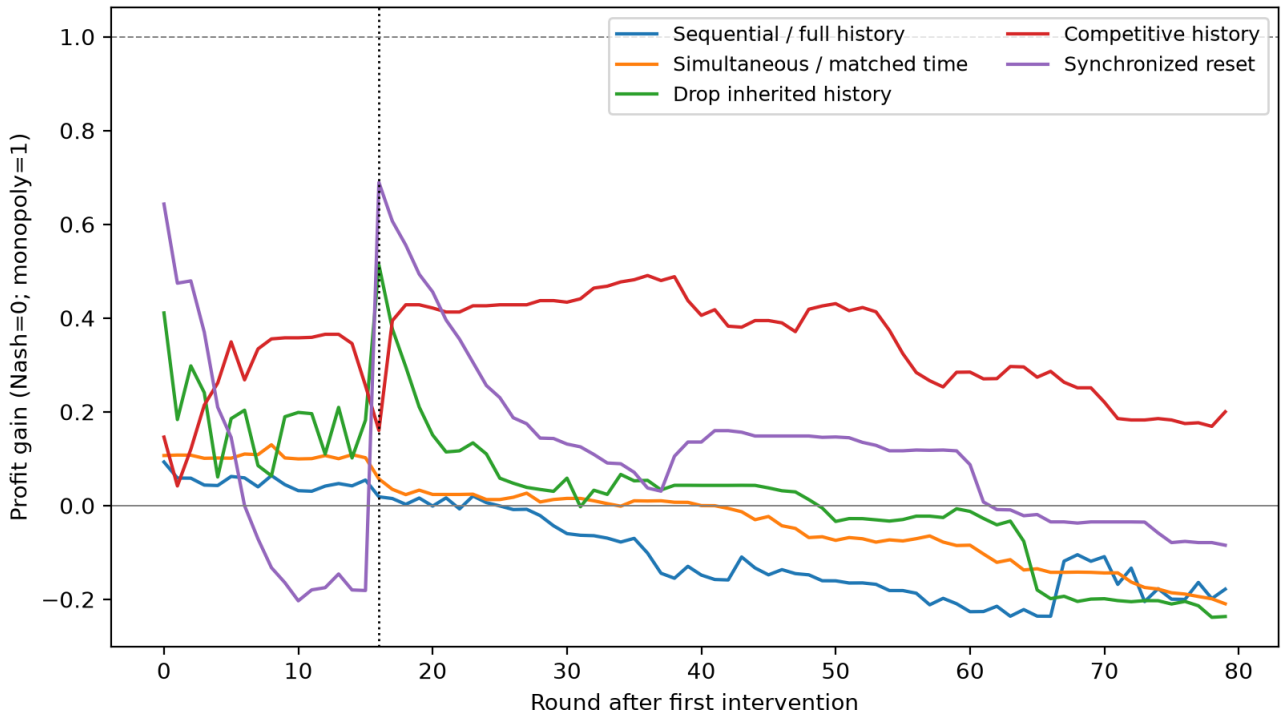

Figure 1. Mean normalized profit gain. Both turnover schedules are scored over the same terminal window after complete replacement. Zero is the Nash benchmark; one is joint monopoly profit.

1. Results and positive controls

RESEARCH DRAFT - REVIEW BEFORE SUBMISSION

Primary comparisons are within the same founder trajectory. Intervals adjust bootstrap tails across the three primary contrasts. Seeds and directions are nested within product context; rounds are not independent samples.

Contrast	Effect	Adjusted interval	Holm p	Contexts
seq_full vs simultaneous_delayed	-0.0590	[-0.3147, 0.1530]	1	12
seq_full vs seq_drop_pre	-0.0710	[-0.4715, 0.3508]	1	12
seq_full vs seq_competitive	-0.4601	[-0.7659, -0.1678]	0.01758	12

Test positive controls completed: 24/24. The PC instruction is explicitly collusion-seeking; its outputs are not evidence of spontaneous formation under neutral instructions.

Control model	Mean terminal gain	Completed
Qwen/Qwen3-14B	0.0000	12
Qwen/Qwen3-8B	-0.1636	12

Deviation response and recovery

Matched probe trials: 24; actual same-round undercuts: 22. The other seller chooses before the forced action is visible and can respond only from the following round.

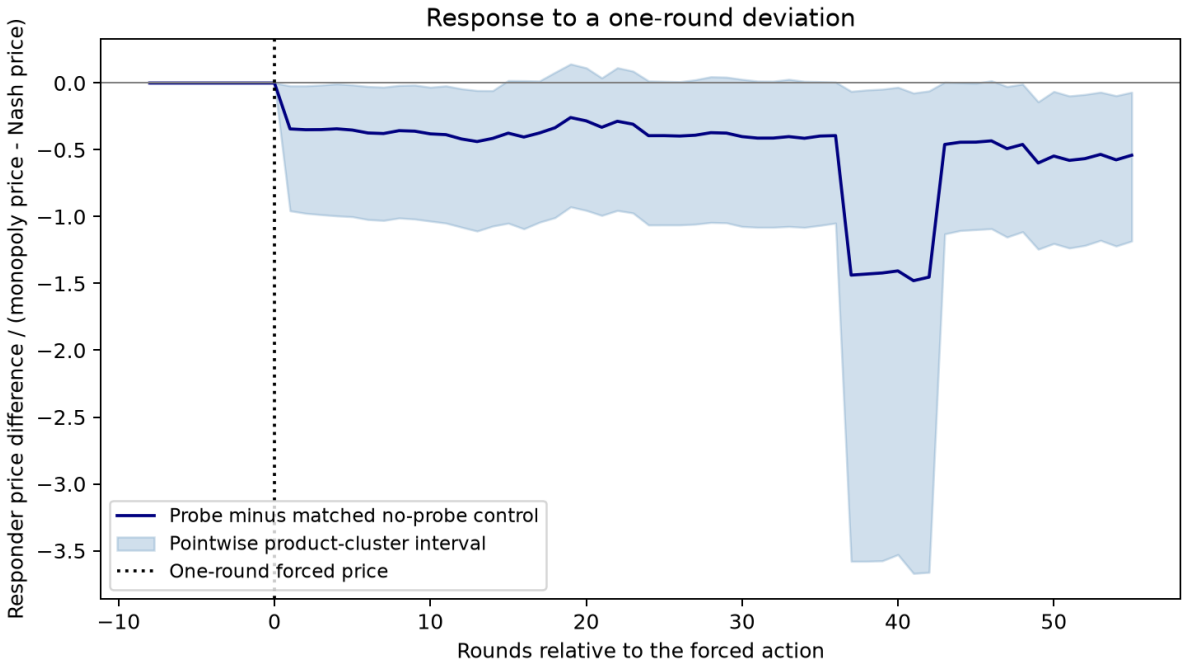

Figure 2. Responder-price difference from its matched no-probe branch. Shading is pointwise product-cluster uncertainty, not a simultaneous band. Recovery or oscillation can arise from reactive anchoring.

2. Design, interpretation, and benchmark correction

Founder instruction: P0; successor instruction: P0. Models: Qwen/Qwen3-8B and Qwen/Qwen3-14B, with both turnover directions. Founder horizon: 64 rounds, selected on development contexts only. Sequential replacements occur at branch rounds 0 and 16; the matched simultaneous replacement occurs at 16. Follow-up: 64 rounds; terminal scoring window: 32.

The early incumbent/successor interaction intentionally differs between schedules. Matching final turnover time removes unequal post-turnover exposure from the primary contrast, but does not isolate an abstract timing effect independent of the histories generated during the gap.

Prompt and decoding are part of the treatment setting

The observation explicitly names a two-seller simulation and supplies the demand formula, both costs and qualities, public prices, and own outcomes. There is no plans-and-insights scratchpad. Non-thinking decoding is constrained to a numeric price line. These choices can change behavior and must not be described as a faithful reproduction of the original Fish et al. prompt setup.

Verified currency-scale correction

The pinned starter payoff uses p/alpha, but its price FOC omits the corresponding 1/alpha derivative. We solve normalized prices x=p/alpha, check residuals, and convert back into currency. The unchanged environment still computes actual demand and payoff.

Nash: 1 - (x_i - c_i)(1 - s_i)/mu = 0. Joint monopoly: 1 - (x_i - c_i)/mu + sum_j((x_j - c_j)s_j)/mu = 0.

Regression tests compare the original symmetric unit-scale solution, verify scale invariance, and check numerical profit derivatives. The correction is a reproducibility contribution, not a substitute for model evidence.

What the comparisons can establish

The main estimates test persistence and history dependence under specified interventions. Positive persistence with a loss under synchronized resets is compatible with transmission through observations. Similar behavior can also reflect anchoring, shared priors, imitation, or pricing errors. The deviation diagnostic narrows the evidence but does not resolve these mechanisms uniquely.

The inherited-histories and replacement-policy motivations build on Calvano et al. (2020), Fish et al. (2024), Eschenbaum et al. (2022), and Keppo et al. (2026). The specific proposed contribution is complete-turnover comparison with controlled history interventions, rather than a claim that collusion, heterogeneity, or memory effects are newly discovered.

Appendix A. Limitations and Dual-Use / Ethical Considerations

Scope and external validity

Real retail records calibrate descriptive context and scale in an assumed logit game; UCI contexts share the normalized economy and Dominick's cost proxies add limited variation, so twelve product clusters are not twelve independent empirical economies. No causal demand elasticities or real cartel labels are estimated.

Shared priors can support similar pricing without inter-agent transmission. Cross-family comparisons also change training, architecture, and native chat templates. Price-only decoding, syntax constraints, finite horizons, initialization, and full-information observations limit generalization. PC-instructed founders must remain separate from neutral founders in every table and claim.

Statistics and missingness

All valid founder histories enter the primary analysis, including low-profit histories. An established-only analysis is secondary. Product-cluster bootstrap intervals can be unstable with few contexts, and sign-flip tests assume a symmetric null. Complete-case comparisons can be biased if failures vary by arm. Invalid model outputs are cached, not repeatedly sampled until favorable; no missing action is imputed.

Recorded missing test arms: 0. The machine-readable quality gates, control failures, and per-arm traces must be inspected alongside aggregate effects. A passed software test is not evidence that the research has adequate power.

Anchoring and the deviation probe

A one-round best-response action is calculated from the previously observed rival price. Near competitive prices it need not be a downward shock, so actual undercut counts are reported. A temporary price reduction and later recovery can occur under simple reactive rules; it is not proof of punishment, intent, or a repeated-game equilibrium.

Dual use and responsible interpretation

The work is an offline audit. It changes no real prices, contacts no firms, and excludes customer identifiers from model inputs. A potential misuse is retaining a harmful pricing convention through agent replacement while presenting the replacement as remediation. The research motivation is to audit successors and inherited observations, not to improve live cartel operation. No real-world evasion capability is claimed.

Reproducibility and authorship

Review preregistration.json, source and data hashes, hardware and concurrency measurements, exact model revisions, raw trajectories, and the validation record. AI assistance was used for implementation and drafting; the submitting author must verify all claims. Preexisting supplied code and literature are attributed. The official template could not be retrieved in this environment, so this PDF is a review draft, not a certified template-compliant submission.

Official submission template and requirements

Use the current template linked on the sprint page. It requires a PDF, a 150-250 word abstract, author details, and a Limitations and Dual-Use / Ethical Considerations appendix. The main report limit is eight pages, excluding references and appendices.
